CHAI is a C++ library providing an array object that can be used transparently in multiple memory spaces. Data is automatically migrated based on copy-construction, allowing for correct data access regardless of location. CHAI can be used standalone, but is best when paired with the RAJA library, which has built-in CHAI integration that takes care of everything.

- If you want to get and install CHAI, take a look at our getting started guide.
- If you are looking for documentation about a particular CHAI function, see the code documentation.
- Want to contribute? Take a look at our developer and contribution guides.

Any questions? Contact chai-dev@llnl.gov
This page provides information on how to quickly get up and running with CHAI.

## 1.1 Installation

CHAI is hosted on GitHub [here](https://github.com). To clone the repo into your local working space, type:

```bash
$ git clone --recursive git@github.com:LLNL/CHAI.git
```

The `--recursive` argument is required to ensure that the `BLT` submodule is also checked out. `BLT` is the build system we use for CHAI.

### 1.1.1 Building CHAI

CHAI uses CMake and BLT to handle builds. Make sure that you have a modern compiler loaded and the configuration is as simple as:

```bash
$ mkdir build && cd build
$ cmake -DCUDA_TOOLKIT_ROOT_DIR=/path/to/cuda ../
```

By default, CHAI will attempt to build with CUDA. CMake will provide output about which compiler is being used, and what version of CUDA was detected. Once CMake has completed, CHAI can be built with Make:

```bash
$ make
```

For more advanced configuration, see *Configuring CHAI*.
1.2 Basic Usage

Let’s take a quick tour through CHAI’s most important features. A complete listing you can compile is included at the bottom of the page. First, let’s create a new ManagedArray object. This is the interface through which you will want to access data:

```cpp
chai::ManagedArray<double> a(100);
```

This creates a ManagedArray storing elements of type double, with 100 elements allocated in the CPU memory.

Next, let’s assign some data to this array. We’ll use CHAI’s forall helper function for this, since it interacts with the ArrayManager for us to ensure the data is in the appropriate ExecutionSpace:

```cpp
forall(sequential(), 0, 100, [=] (int i) {
    a[i] = 3.14 * i;
});
```

CHAI’s ArrayManager can copy this array to another ExecutionSpace transparently. Let’s use the GPU to double the contents of this array:

```cpp
forall(cuda(), 0, 100, [=] __device__ (int i) {
    a[i] = 2.0 * a[i];
});
```

We can access the array again on the CPU, and the ArrayManager will handle copying the modified data back:

```cpp
forall(sequential(), 0, 100, [=] (int i) {
    std::cout << "a[" << i << "] = " << a[i] << std::endl;
});
```
The file `src/examples/example.cpp` contains a brief program that shows how CHAI can be used. Let’s walk through this example, line-by-line:
In addition to the normal options provided by CMake, CHAI uses some additional configuration arguments to control optional features and behavior. Each argument is a boolean option, and can be turned on or off:

-DENABLE_CUDA=Off

Here is a summary of the configuration options, their default value, and meaning:

<table>
<thead>
<tr>
<th>Variable</th>
<th>Default</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>ENABLE_CUDA</td>
<td>Off</td>
<td>Enable CUDA support.</td>
</tr>
<tr>
<td>ENABLE_HIP</td>
<td>Off</td>
<td>Enable HIP support.</td>
</tr>
<tr>
<td>ENABLE_GPU_SIMULATION_MODE</td>
<td>Off</td>
<td>Simulates GPU execution.</td>
</tr>
<tr>
<td>ENABLE_UM</td>
<td>Off</td>
<td>Enable support for CUDA Unified Memory.</td>
</tr>
<tr>
<td>ENABLE_CNEM</td>
<td>Off</td>
<td>Enable cnmem for GPU allocations.</td>
</tr>
<tr>
<td>ENABLE_ implicit_conversions</td>
<td>On</td>
<td>Enable implicit conversions between ManagedArray and raw pointers</td>
</tr>
<tr>
<td>DISABLE_R M</td>
<td>Off</td>
<td>Disable the ArrayManager and make ManagedArray a thin wrapper around a pointer.</td>
</tr>
<tr>
<td>ENABLE_TESTING</td>
<td>On</td>
<td>Build test executables.</td>
</tr>
<tr>
<td>ENABLE_BENCHMARKS</td>
<td>On</td>
<td>Build benchmark programs.</td>
</tr>
</tbody>
</table>

These arguments are explained in more detail below:

- **ENABLE_CUDA** This option enables support for GPUs using CUDA. If CHAI is built without CUDA, HIP, or GPU_SIMULATION_MODE support, then only the CPU execution space is available for use.

- **ENABLE_HIP** This option enables support for GPUs using HIP. If CHAI is built without CUDA, HIP, or GPU_SIMULATION_MODE support, then only the CPU execution space is available for use.

- **ENABLE_GPU_SIMULATION_MODE** This option simulates GPU support by enabling the GPU execution space, backed by a HOST umpire allocator. If CHAI is built without CUDA, HIP, or GPU_SIMULATION_MODE support, then only the CPU execution space is available for use.
• ENABLE_UM This option enables support for Unified Memory as an optional execution space. When a ManagedArray is allocated in the UM space, CHAI will not manually copy data. Data movement in this case is handled by the CUDA driver and runtime.

• ENABLE_CNEM This option enables the use of the cnmem library for GPU allocations. The cnmem library provides a pool mechanism to reduce the overhead of allocating memory on the GPU.

When ENABLE_CNEM is set to On, you must tell CMake where to find the cnmem library. This can be done by setting the cnem_DIR variable, for example:

• ENABLE_IMPLICIT_CONVERSIONS This option will allow implicit casting between an object of type ManagedArray<T> and the corresponding raw pointer type T*. This option is disabled by default, and should be used with caution.

• DISABLE_RM This option will remove all usage of the ArrayManager class and let the ManagedArray objects function as thin wrappers around a raw pointer. This option can be used with CPU-only allocations, or with CUDA Unified Memory.

• ENABLE_TESTING This option controls whether or not test executables will be built.

• ENABLE_BENCHMARKS This option will build the benchmark programs used to test ManagedArray performance.
CHAPTER 4

Code Documentation
This document is intended for developers who want to add new features or bugfixes to CHAI. It assumes you have some familiarity with git and GitHub. It will discuss what a good pull request (PR) looks like, and the tests that your PR must pass before it can be merged into CHAI.

## 5.1 Forking CHAI

If you aren’t a CHAI developer at LLNL, then you won’t have permission to push new branches to the repository. First, you should create a fork. This will create a copy of the CHAI repository that you own, and will ensure you can push your changes up to GitHub and create pull requests.

## 5.2 Developing a New Feature

New features should be based on the develop branch. When you want to create a new feature, first ensure you have an up-to-date copy of the develop branch:

```
$ git checkout develop
$ git pull origin develop
```

You can now create a new branch to develop your feature on:

```
$ git checkout -b feature/<name-of-feature>
```

Proceed to develop your feature on this branch, and add tests that will exercise your new code. If you are creating new methods or classes, please add Doxygen documentation.

Once your feature is complete and your tests are passing, you can push your branch to GitHub and create a PR.
5.3 Developing a Bug Fix

First, check if the change you want to make has been fixed in develop. If so, we suggest you either start using the develop branch, or temporarily apply the fix to whichever version of CHAI you are using.

Assuming there is an unsolved bug, first make sure you have an up-to-date copy of the develop branch:

```
$ git checkout develop
$ git pull origin develop
```

Then create a new branch for your bugfix:

```
$ git checkout -b bugfix/<name-of-bug>
```

First, add a test that reproduces the bug you have found. Then develop your bugfix as normal, and ensure to make test to check your changes actually fix the bug.

Once you are finished, you can push your branch to GitHub, then create a PR.

5.4 Creating a Pull Request

You can create a new PR here. GitHub has a good guide to PR basics if you want some more information. Ensure that your PR base is the develop branch of CHAI.

Add a descriptive title explaining the bug you fixed or the feature you have added, and put a longer description of the changes you have made in the comment box.

Once your PR has been created, it will be run through our automated tests and also be reviewed by RAJA team members. Providing the branch passes both the tests and reviews, it will be merged into RAJA.

5.5 Tests

CHAI’s tests are all in the test directory, and your PR must pass all these tests before it is merged. If you are adding a new feature, add new tests.
